Title : Conditioned Orientating Reflex and Its Extinguishing in Young Children.

Orig Pub : Sb. nauchn. tr. Ivanovsk. med. in-ta, 1957, vyp. 12. 7-14

Abstract : In 17 children in the age group of 4 months - 1 year, 4 months, a conditioned orientating reflex (COR) was worked out to the combination of a buzzer with a red light. The unconditioned reaction of turning the head to the light appeared at 3-4th months. In children older than 7 months COR arose at 2-4th combination and was stable. Extinguishing of COR occurred slower than its

TITLE: Stub Delay System for Paramagnetic Travelling Wave Amplifier in the Centimeter Band

PERIODICAL: Radiotekhnika i elektronika, 1961, Vol.6, No.3, pp. 406-409

TEXT: The article describes work based on that of De Grasse et al (Ref.1; Bell System Techn.J., 1959, 38, 2, March, 305). The main difference from the earlier system consists in the wide-band matching circuit (Fig.3) and the introduction of the pumping signal. The matching circuit provides smooth transformation of the high-frequency field of the delay system to the  $H_{10}$ -wave in the rectangular waveguide. The pumping signal is fed through a rectangular waveguide entering the stub wall at the centre of the delay system on the side of the rose so that the E-pumping vector would be perpendicular to the side plane of the stub system. To decouple the working and pumping channels, the planes of polarization of the two channels were taken mutually perpendicular. Making the narrow wall of the fundamental waveguide small enough

VX

Stub Delay System for Paramagnetic Travelling Wave Amplifier in the Centimeter Band

so that at pumping frequency this channel will be a cut-off waveguide, the two channels are sufficiently decoupled. The fundamental signal cannot enter the pumping channel since for it the pumping channel waveguide is also cut off. The entire system was designed for immersion in a dewar flask. Experimentally obtained dispersion characteristics for a stub system of height 0.222 are given in Fig.4, and the insertion loss of the system in Fig.6.

TW MASER FOR AMPLIFICATION IN THE 3-cm BAND (USSR)

Karlova, Ye. K., N. V. Karlov, A. M. Prokhorov, and Ye. G. Solov'yev.  
Priory i tekhnika eksperimenta, no. 2, Mar-Apr 1963, 107-110.

S/120/63/000/002/025/041

Performance and construction details are described for a 3-cm traveling-wave maser which used a waveguide section containing two ruby rods attached along the base of a comb delay array on opposite sides of the teeth. The ruby had a  $\text{Cr}^{3+}$  concentration of about 0.07% and was 2 mm in diameter by 100 mm long; the red (isolating) ruby rod had a  $\text{Cr}^{3+}$  concentration of 1 to 2%. The external hf magnetic field was elliptically polarized in the plane of the comb, with its major axis normal to the traveling-wave line of propagation, in such a manner that at an eccentricity of 1.5 the energy density of the forward wave on one side of the comb array exceeded backward-wave density by 25 times. Measurement of energy density in the delay section was achieved by comparison of the EPR absorption line intensity in a DPPH sample, when the latter was located alternately in the feed-in and delay sections of the waveguide. The amplifier was

TITLE: Millimeter-band receiver based on an InSb photoconductor

SOURCE: Pribery i tekhnika eksperimenta, no. 2, 1966, 191-194

TOPIC TAGS: crystal detector, photoresistor, photoconductor, indium alloy

ABSTRACT: The design and performance of a low-noise millimeter-wave receiver based on an InSb detector are described. The InSb element, which at liquid He temperature acts as a photoresistor to incident millimeter rf, was n-type, with a rated carrier mobility of  $3 \times 10^5$  cm<sup>2</sup>/v·sec, and was cut from a single crystal to dimensions of 4 x 1 x 1 mm. At an operating temperature of 4.2K, detector resistance was in the range of 130—150 ohms. The crystal, together with a carbon-ballast resistor, was mounted in a 3.2-mm diameter waveguide, which was fed by a klystron via a tapered polyethylene insert in the guide, and the assembly was immersed in the He cryostat (see Fig. 1). Special efforts were taken to shield the crystal and receiver circuitry because of the great sensitivity and bandpass of the InSb element. The incoming

$R_0$  - InSb resistor;  
 $R$  - ballast resistor.

Card 2/3

signal was dual-modulated: at 72 cps by oscillation of a slot attenuator in the guide and at 3 kc by modulation of the klystron supply voltage. By also using synchronous detection and low-noise receiver components, the authors obtained reception considerably better than that of usual (type D-407) crystal diodes, under the same test conditions. The relative improvement in sensitivity of the InSb element varied from 20 db at  $\lambda = 4$  mm to 3 db at  $\lambda = 0.6$  mm; by lowering the He temperature to 1.8K, these gains could be improved another 3—5 db. The stability and zero drift of this receiver were considered very good, with consistency of data maintained over several months of operation, provided the copper leads to the crystal were not resoldered. However, the InSb element was found to lose its sensitivity several months after being removed from the receiver. The authors conclude that their receiver is comparable in sensitivity to some of the best present superhet types in the millimeter band, and they suggest that it can be used in radiospectroscopy and radioastronomy. "The authors are extremely

1619. SILICON MIXER DIODES. J. Kandovsky and M. Valdek. 641.314.63  
 Mikrovlny Ondy, Vol. 17, No. 12, 1978-79, 1504-1508. In Czech.  
 Silicon crystal diodes are compared with Ge-crystal rectifiers  
 and the technology of the preparation of pure Si crystals from SiCl<sub>4</sub>  
 is briefly outlined. The theory of diode detection is dealt with and,  
 in particular, the detection of microwaves is discussed in some  
 detail. Some Czechoslovak-made Si diodes of the point-contact type  
 are described. One type of diode operates at 3 cm wavelengths and  
 has a forward resistance of 500 Ω, reverse resistance of 6000 Ω,  
 and mixing loss of 8.5 dB and maximum noise temperature of 4. The  
 other type is used at wavelengths of 10 cm and has the same resist-  
 ances as the 3 cm diodes, but its mixing loss is 10 dB and the noise  
 temperature is 5.

TITLE: New Trends in Semiconductor<sup>22</sup> Techniques for Very High Frequencies<sup>8</sup>

PERIODICAL: Slaboproudý obzor, 1960, Vol.21, No.9, pp 529-535

TEXT: This is a revised version of a paper read at a meeting of the Scientific-Technical Council of the Vacuum Technique Section of TESLA, Rožnov on April 26, 1959. The author reviews information published in literature on semiconductor components intended for use at ultra-high frequencies. First, the various factors determining the upper limit of the frequencies of diodes and transistors are considered. In the further parts of the paper methods are described which enable increasing the limit frequency. Finally, some possible applications are described. The survey covers literature published up to early 1959. The described possible principles of amplification, mixing and generation of high frequencies by means of semiconductor diodes provide great potentialities in a number of fields. Since in most cases nonlinear reactances are used, the self-generated

TITLE: Tunnel diodes under development in Czechoslovakia

PERIODICAL: Referativnyy zhurnal. Avtomatika i radioelektronika,  
no. 6, 1962, abstract 6-4-20 y (Automatizace, 1961, 4,  
no. 10, 292-293)

TEXT: Development of tunnel diodes in Czechoslovakia is undertaken at the National Institute of Telecommunication im. A.S. Popov in Prague. A series of germanium diodes has been designed, using n-type germanium with spec. resistivity  $\approx 0.001$  ohm-cm, alloyed with arsenic. The junction is formed by alloying an indium pellet with an admixture of gallium. The junction area is reduced by electrolytic etching. Parameters of diodes DT1, DT2, DT3 are tabulated. Typical values:  $I_p/I_v \approx 6$ ;  $U_p \approx 50$  mV;  $U_v \approx 300$  mV;  $C_v/I_p \approx 10-20$  pF/ma. The best values attained are  $I_p/I_v = 11$  and  $C_v/I_p = 3$  pF/ma. Possible applications of the above diodes are discussed. 2 references. [Abstracter's note: Complete translation.]

AUTHOR: Karlovský, Jaroslav, Engineer

TITLE: Silicon Detector Diodes for Centimetre Waves

PERIODICAL: Slaboproudý obzor, 1961, Vol. 22, No. 1,  
pp. 20 - 24

TEXT: The main parameter of a detector diode is its detection sensitivity which is defined by:

$$\beta = I_{\text{r}} / P_{\text{vf}} \quad (1)$$

where  $I_{\text{r}}$  is the rectified current and

$P_{\text{vf}}$  is the high-frequency power supplied to the diode.

The high-frequency circuit of a silicon diode can be represented by a series resistance  $R_{\text{s}}$  followed by a parallel combination of a resistance  $R_{\text{p}}$  and a capacitance

C. The current-voltage characteristic of the rectifier  
Card 1/6

87980

Z/039/61/022/001/003/006  
E192/E382

Silicon Detector Diodes for Centimetre Wave§

$$\beta_o = \frac{\alpha}{2 \left( 1 + \frac{R_s}{R_b} \right)^2} \quad (16)$$

where  $\alpha$  is a parameter depending on the shape of the current-voltage characteristic, and

$C$ ,  $R_s$ ,  $R_b$  are the parameters of the equivalent circuit of the diode.

As a current source in a receiver, the diode can be assumed to have an output resistance  $R_b$ . The noise voltage produced by this source is therefore given by:

Card 3/6

87980

Z/039/61/022/001/003/006  
E192/E382

Silicon Detect or Diodes for Centimetre Waves

$$U_{s1}' = \sqrt{4kT \cdot \Delta f \cdot R_b} \quad (22)$$

where  $k$  is the Boltzmann constant,  
 $T$  is the absolute temperature of the diode, and  
 $\Delta f$  is the bandwidth occupied by the noise.  
The signal-to-noise ratio at the output of the receiver can  
therefore be expressed as;

$$\frac{U_2}{U_{s2}} = \frac{\beta \cdot P_{vf} \cdot R_b}{\sqrt{4kT \cdot \Delta f \cdot (R_b \cdot t + R_e)}} \quad (27)$$

Card 4/6

87980

Z/039/61/022/001/003/006  
E192/E382

# Silicon Detector Diodes for Centimetre Waves

where  $t$  is a coefficient taking into account the biasing voltage of the diode and  $R_e$  is the equivalent noise resistance of the input tube of the receiver.

It is useful to define the so-called tangential sensitivity of the receiver. This is defined as the high-frequency input power  $P_o$  such that the signal-to-noise ratio

$U_2/U_{s2} = 2$ . This quantity can easily be measured by using a high-frequency pulse, whose effective amplitude is twice the noise amplitude. Methods of measuring the detection sensitivity, the output resistance and the tangential sensitivity of the diode are discussed in some detail. A simple potentiometer circuit for measuring the detection sensitivity  $\beta$  is shown and also a circuit for measuring the output resistance is given. The equipment

Card 5/6

E192/E382

Silicon Detector Diodes for Centimetre Waves

necessary for measuring the tangential sensitivity is illustrated in a block schematic and a detailed circuit diagram of the pulse-generator employed in this measurement is shown. It is concluded that silicon detector diodes can be used at centimetre waves provided the signal available is not lower than  $0.01 \mu W$ . There are 9 figures and 5 references: 1 Czech and 4 non-Czech.

TITLE: A novelty: Wireless microphone

PERIODICAL: Sdělovací technika, no. 2, 1962, 70

TEXT: The device described is in effect a frequency-modulated miniature transmitter. Detailed circuit diagram of the system is given in Fig. 1. In this, a transistor  $T_1$  operates as an oscillator. The transistor is OC170 and is specially chosen in order to be capable of operating at 100 Mc/s. The transistor operates as a common-base oscillator with the tuned circuit in the collector, the feedback being taken from a tapping on the tuning coil through the capacitor  $C_1$  to the emitter. The oscillator is followed by a high-frequency amplifier stage based on the transistor  $T_2$ , which is coupled to the oscillator by the coil  $L_2$ . The collector of  $T_2$  contains the tuned circuit  $L_3$ - $C_6$ , which is coupled to the antenna. The signal from a

Card 1/3

A novelty ....

Z/014/62/000/002/003/003  
E192/E382

dynamic microphone is amplified by a single-stage audio-amplifier based on  $T_3$ . The amplified audio-signal is applied to the base of  $T_1$  through the coupling condenser  $C_7$ . The low frequency  thus changes the operating voltage between the collector and the base of  $T_1$ . This results in the modulation of the collector-base capacitance of  $T_1$ , which is connected in parallel with the tuned circuit. In this way, the oscillator undergoes frequency-modulation. The system is fed from a 13.5 V battery and produces an output of 20 mW in the antenna. The frequency-modulation deviation is 100 kc/s and the bandwidth of the audio-channel extends from 20 c.p.s. to 20 kc/s (at 30 db). The microphone can be used at distances of 50 - 100 m. There are 2 figures.

AUTHOR: Karlovský, Jaroslav, Engineer

TITLE: Voltage-current characteristic of the Esaki diode

PERIODICAL: Stelovaci technika, no. 5, 1962, 172

TEXT: The average squared value of the noise current of an Esaki diode is expressed by:

$$\overline{I_s^2} = 2e(I_e + I_z) \cdot \Delta f \quad (5)$$

where  $I_e$  is the Esaki current and

$I_z$  is the Zener current.

It is therefore necessary to determine  $I_e$  and  $I_z$  from the measured characteristic  $I = f(U)$ . It is shown that the relationship between the currents is given by:

$$I_e = I_z \exp \frac{eU}{kT} \quad (8)$$
